Abstract

To better understand the interaction mechanisms of plant surfaces with polar organic compounds, sorption of 4-chlorophenol, 2,4-dichlorophenol, and 2,4,6-trichlorophenol by fruit cuticles (i.e., tomato, apple, and pepper), and potato tuber periderm were investigated. The roles of cuticular components (waxes, cutin, cutan and sugar) on sorption of chlorophenols are quantitatively compared. Cutin and waxes govern the sorption capacity of bulk apple cuticle by hydrophobic interactions. Potato periderm with highest sugar content exhibits the lowest sorption capability for the chlorophenols. With the increase of hydrophobicity (i.e., K_{ow}) of sorbate, the relative contribution of lipophilic components (wax, cutin and cutan) on total sorption increases, however, the ratios of K_{oc} to K_{ow} decreases due to increasing ionization degree of sorbates.

Key words: potato periderm; fruit cuticle; chlorophenol; sorption; waxes; cutin

DOI: 10.1016/S1001-0742(11)60891-7

Introduction

Plant cuticles (above-ground parts) along with periderm (below-ground) covered the outmost of higher plants play a significant role in the physiology and autecology of plant. Plant cuticles serve as the initial contact of plant tissue with agrichemicals and environmental contaminants (Chen et al., 2005; Koch et al., 2008; Wang et al., 2008). Cuticle is mainly made up of the lipid biopolymer, e.g., waxes, cutin and cutan, and non-lipid components, e.g., polysaccharides, polypeptides and phenolic compounds (Müller and Riederer, 2005; Li and Chen, 2009). Waxes are the extractable lipids by organic solvents, whereas cutin (depolymerizable ester-bound lipids) and cutan (non-saponifiable biopolymer) are insoluble polymeric lipids (Li and Chen, 2009). As an initial process of cuticle (periderm) penetration, sorption process dominated the efficiency of agrichemicals plant uptake and the degree of contaminants plant accumulation (Riederer and Schnöherr, 1984; Buchholz, 2006). Several studies were conducted to illustrate the sorption characteristics and mechanisms of nonpolar organic compounds by plant cuticles (Riederer and Schnöherr, 1984; Sabljic et al., 1990; Chefetz, 2003; Chen et al., 2005, 2008; Chen and Li, 2007; Li and Chen, 2009; Li et al., 2010). Plant cuticles were demonstrated to be highly efficient sorbents for nonpolar organic compounds (Riederer and Schnöherr, 1984), and their sorption coefficients were predictable from the oc-

tanol/water partition coefficients (K_{ow}) of sorbates (Sabljic et al., 1990). Recently, the relative role of each cuticle composition on total sorption behavior was illustrated (Chefetz, 2003; Chen et al., 2005, 2008; Shechter et al., 2006; Li and Chen, 2009; Li et al., 2010). Wax and cutin were the main sorption contributors of cuticle for nonpolar organic pollutants, whereas polar sugar component played a negative role. The sugar component with poor affinity exhibited restrictive effect on the powerful sorptive regions of cuticle (Chefetz, 2003; Chen et al., 2005; Li and Chen, 2009). Sorption coefficients of nonpolar organic pollutants were sharply decreased after the removal of cutin, but increased with the consumption of sugar component via acid hydrolysis (Chefetz, 2003; Shechter et al., 2006; Chen et al., 2008; Li et al., 2010).

In comparison with nonpolar organic contaminants (NOCs), few studies focused on sorption property and mechanism of polar and ionizable organic pollutants onto plant cuticles. Differently from NOCs, ionizable organic pollutants exist either as non-dissociated (molecular) or as dissociated species (organic ion) in aqueous solution. Sorption properties of the two species may be distinctive. Dissociated species often has low partition coefficients with plant cuticles, because ionic groups are surrounded by water molecules and the hydrated organic molecules are essentially insoluble in cutin and waxes (Schnöherr, 2006). Non-dissociated polar organic molecules are expected to affinity with cutin and waxes through hydrophobic interaction, as well as with polar groups of plant cuticle via specific interaction. Thus, the relative role of each com-

* Corresponding author. E-mail: blchen@zju.edu.cn

ponents of cuticle on sorption of polar organic pollutants would be quite different with that of NOCs. Taking 1-naphthol as an example, sorption coefficient of pepper cuticle did not increase but slightly decreased after sugar removal, suggesting that sugar component seems to play a positive role in uptake of polar organic pollutants (Chen et al., 2005). However, sugar removal resulted in an increase of sorption capacity of 1-naphthol onto tomato cuticle (Chen and Li, 2007). Therefore, more works are needed to well understand sorption of ionizable organic pollutants with plant surface since most foliar agrichemicals and many environmental contaminants are ranked to this species.

The main objective of this study is to elucidate relationship between sorption properties of ionizable organic pollutants and compositional characteristics of plant cuticles. Three chlorophenols, i.e., 4-chlorophenol, 2,4-dichlorophenol, and 2,4,6-trichlorophenol, were selected as representatives of ionizable organic pollutants, because they are widely presented in the effluents from pesticides, dyestuffs, pharmaceuticals, petrochemicals industries (Kah and Brown, 2006; Núñez-Gaytán et al., 2010). Three typical fruit cuticles, such as apple, pepper and tomato, as well as potato periderm were chosen as models of plant surfaces.

1 Material and methods

1.1 Isolation of plant cuticle and periderm fractions

Bulk cuticles of tomato (*Solanum lycopersicum*, TC1) and green pepper (*Capsicum annuum*, PC1), as well as potato periderm fraction (*Solanum tuberosum*, PP1) were selected and isolated as described previously (Chen et al., 2005; Li and Chen, 2009). Their composition characteristics have been described (Chen et al., 2005; Li and Chen, 2009), and the yields of the cuticular components were cited as follows: respective waxes content of 6.2%, 6.4% and 13.4% for pepper cuticle, tomato cuticle and potato periderm; cutin/suberin content of 64.8%, 69.5% and 21.5%; cutan/suberan content of 7.9%, 0% and 21.2%; sugar content of 21.5%, 24.0% and 43.9%.

Apple cuticle was isolated from apple fruits (*Malus domestica*) by enzymatic method modified from procedure described by Orgell (1955) and Yamada et al. (1964). Briefly, cuticle sheets were manually peeled from fresh apple fruits, and then were incubated in a mixture of cellulase (2%, W/V), pectinase (2%, W/V), and NaN₃ (1 mmol/L) in citric acid buffer (20 mmol/L, pH 3.8) at room temperature. Enzyme solution was refreshed periodically

until the cuticle fully separated from the tissue. Subsequently, cuticles were washed extensively in deionized water, oven-dried at 60°C, ground, and sieved (< 0.18 mm) for sorption experiments. This procedure yielded the bulk apple cuticle fraction (AC1). Six apple cuticular fractions, i.e., dewaxed apple cuticle (AC2), nonsaponifiable fraction (AC3), cutan (dewaxed-nonsaponifiable fraction AC4), dewaxed-hydrolyzed cuticle (AC5), desugared residue (AC6) and waxes fraction (AW), were obtained according to the procedure described previously (Chen and Li, 2007; Li and Chen, 2009).

1.2 Characterization of the apple cuticular fractions

Elemental (C, H, N) analyses for the apple cuticular fractions (AC1–AC6, AW) were conducted using an EA 112 CHN elemental analyzer (Thermo Finnigan, USA), while the oxygen content was calculated by the mass difference because the ash content was neglected. The H/C and (O+N)/C atomic ratios were calculated. Because the tomato cuticle, pepper cuticle, potato periderm used in the current study were the same as our previous reports (Chen et al., 2005; Li and Chen, 2009), the CHNO data for these samples were cited from the reference.

1.3 Batch sorption experiment

4-Chlorophenol (CP), 2,4-dichlorophenol (DCP), and 2,4,6-trichlorophenol (TCP) were chosen as representatives of polar organic pollutants, and their selected physicochemical properties are listed in Table 1. Sorption of sorbate onto the isolated cuticular and peridermal fractions (AC1–AC6, AW, TC1, PC1 and PP1) was performed at (25 ± 0.5)°C by a batch equilibrium technique (Chen et al., 2008). Each isotherm consisted of eight or ten concentration points, and each point (including the control and calibration) was run in duplicate. The background solution included 0.01 mol/L CaCl₂ (to keep a constant ionic strength) and 200 mg/L NaN₃ (to inhibit incidental biodegradation). The pH of the solution was kept original without any adjustment, i.e., pH 6.9 for 400 mg/L 4-chlorophenol, pH 6.4 for 400 mg/L 2,4-dichlorophenol, and pH 5.5 for 250 mg/L 2,4,6-trichlorophenol. The sorption properties of each compound to plants or plant components were generated in the different pH environment. To compare their sorption properties, the degree of ionization (α) of the sorbates at different pH values were calculated, i.e., $\alpha = 0.36\%$ for 4-chlorophenol at pH 6.9, $\alpha = 3.23\%$ for 2,4-dichlorophenol at pH 6.4, and $\alpha = 20.1\%$ for 2,4,6-trichlorophenol at pH 5.5. The 8-mL vials were filled with sorbate solution to minimize the headspace volumes of the vial and sealed with alu-

2,4,6-Trichlorophenol (TCP)	197.45	800	4.02	6.10	1.01	0.08	0.82

M: molecular weight; *S_w*: water solubility; *K_{ow}*: octanol-water partition coefficient; p*K_a*: dissociated constant; π^* : polarity/polarizability parameter; β_m : hydrogen-bonding acceptor parameter; α_m : hydrogen-bonding donor parameter. Data of π^* , β_m , and α_m were obtained from the reference of Kamlet et al., 1988.

minimum foil-lined Teflon screw caps to avoid sorbate's evaporation, and then agitated in the dark for 3 days. The solution was separated by centrifugation at 4000 r/min for 20 min. Supernatant concentrations of the tested sorbate were measured with an Agilent 1200 High Performance Liquid Chromatograph (HPLC, USA) fitted with G1314B variable wavelength detector and Agilent Eclipse XDB-C 18 column. The concentrations in the control groups were also determined, and remained the same during the experimental period. Because of minimal sorption by the vials, and negligible losses from evaporation, biodegradation and photodegradation, the sorbed amount was then determined by difference in aqueous concentration between nominal aqueous concentration without sorbent and with sorbent.

1.4 Data analysis

The Freundlich parameters (K_f and N) were calculated using the logarithmic form of Eq. (1):

$$Q = K_f \times C_e^N \quad (1)$$

where, Q (mg/kg) is the sorbed amount per unit weight of sorbent; C_e (mg/L) is the equilibrium concentration of sorbate; K_f ((mg/kg)/(mg/L) ^{N}) is the Freundlich capacity coefficient, and N (dimensionless) describes the isotherm curvature. Sorption coefficients (K_d) were calculated from the slope of the linear isotherms. The K_{oc} is the carbon-normalized K_d , i.e., $K_{oc} = K_d/f_{oc}$ (f_{oc} is the carbon level

of sorbent). K_{owc} is the carbon-normalized K_{ow} ($K_{owc} = K_{ow}/f_{oc}$, f_{oc} is the percentage of carbon content of octanol, i.e., 73.8%). For apple cuticle, the relative contribution (RC) of each component to the total sorption was estimated by the ratio of the $f_i K_{d,i}$ (where i represents wax, cutin, cutan, and sugar) to K_d of bulk apple cuticle (Li and Chen, 2009).

2 Results and discussion

2.1 Characterization of plant cuticles

The mass fractions and elemental compositions of isolated apple cuticular fractions (AC1–AC6, and AW) are listed in Table 2, which is similar to previous report (Li and Chen, 2009). Cutan exhibited the highest aromatic nature.

2.2 Sorption of plant cuticles and periderm

Sorption isotherms of three chlorophenols to bulk fruit cuticles (AC1, PC1 and TC1) and potato periderm (PP1) are presented in Fig. 1. Isotherms fit well to the Freundlich equation, and the regression parameters are listed in Table 3. The sorption isotherms are apparently linear, suggesting that the dominant mechanism is partition (hydrophobic interaction). For 4-chlorophenol, the magnitude of sorption coefficients (K_d) are in the order of pepper cuticle (PC1, 155 L/kg) > apple cuticle (AC1, 124 L/kg)

^aAll sorbents were the bulk plant skins; ^b the Freundlich parameters (K_f and N) were calculated using the logarithmic form of Eq. (1); R^2 is regression coefficient; ^c K_d is the sorption coefficient ($K_d = Q/C_e$), calculated from the slope of linear equation; ^d K_{oc} is the carbon-normalized sorption coefficient ($K_{oc} = K_d/f_{oc}$); ^e K_{owc} is the carbon-normalized octanol-water partition coefficient of chlorophenols ($K_{owc} = 332, 1745, 14188$ for 4-chlorophenol, 2,4-dichlorophenol, and 2,4,6-trichlorophenol, respectively); ^f n is the number of sorption data.

> tomato cuticle (TC1, 117 L/kg) > potato periderm (PP1, 31.9 L/kg). The K_{oc}/K_{owc} ratios for 4-chlorophenol range 0.20–0.73 (Table 3), much lower than those of phenanthrene ($K_{oc}/K_{owc} = 0.90$ – 2.72) with these four plant surfaces (Chen et al., 2005; Li and Chen, 2009). This may be attributed to that the polar function group (–OH) of 4-chlorophenol significantly decreases the affinity for plant cuticles. Magnitude of sorption increases with the increase in sorbate's K_{ow} , e.g., K_d (2,4,6-trichlorophenol) > K_d (2,4-dichlorophenol) > K_d (4-chlorophenol). For the tested polar chemicals, potato periderm shows the poorest affinity due to its highest sugar content. Tomato cuticle exhibits most sensitive to the hydrophobicity of sorbates, and the K_d value for 2,4,6-trichlorophenol is up to 12-times higher than 4-chlorophenol, while for the other plant cuticles the ratio of K_d (2,4,6-trichlorophenol) to K_d (4-chlorophenol) are about 6–9. Considering the strong affinity of cutin with organic compounds via hydrophobic interaction, the highest cutin content of tomato cuticle (69.5%, Table 2) is accounted for its biggest increase in K_d with increasing K_{ow} of the sorbates. In the previous study with the same content of cutin in tomato cuticles, the same trends were observed (Li and Chen, 2009). That could explain that the presence of cutin plays the critical role in strong affinity.

Although the enhancement affinity with plant cuticles during the increase of sorbates' K_{ow} was observed, however, the ratios of K_{oc}/K_{owc} decreased with increasing ionization degree of the sorbates ($\alpha = 1/(1+10^{(pK_a-pH)})$), i.e., 2,4,6-trichlorophenol ($\alpha = 20.1\%$ at pH 5.5) > 2,4-dichlorophenol ($\alpha = 3.23\%$ at pH 6.4) > 4-chlorophenol ($\alpha = 0.36\%$ at pH 6.9). These indicate that the affinity of plant cuticle with organic molecular species is much stronger than the ionic species of organic compound.

2.3 Sorption isotherms of apple cuticular fractions

Sorption isotherms of isolated apple cuticular fractions (AC1–AC6 and AW) are presented in Fig. 2. Isotherms fit well to the Freundlich equation, and the regression pa-

rameters are listed in Table 4. All apple cuticular fractions (except AC4) presented linear isotherms, suggesting the dominant sorption mechanism was the partitioning process into organic phase.

Because of the heterogeneous nature, sorption of bulk plant cuticle is contributed from a series of interactions of different cuticular components with sorbate. However, few studies dealt with the effects of physicochemical properties of sorbate (e.g., hydrophobic nature and polarity) on the sorption characteristic of different cuticular components (such as waxes, cutin, cutan and sugar). K_d of 4-chlorophenol on AW is 57.8 L/kg, which is much lower than the sorbate's K_{ow} value ($K_{oc}/K_{owc} = 0.222$). The K_d ratio of waxes (AW) to bulk cuticle (AC1) is 0.47 (Table 4), suggesting that the contribution of waxes to the total sorption of apple bulk cuticle is relatively low (17.4%, Table 6). With increase in K_{ow} value, the respective K_d value of AW increases to 194 L/kg for 2,4-dichlorophenol and 517 L/kg for 2,4,6-trichlorophenol, and their relative contribution of wax to total sorption increases correspondingly to RC = 18.1% and 24.5%. It is also worth noting that the K_{oc}/K_{owc} value for phenanthrene (nonpolar) on AW (2.16) is larger than that of 2,4,6-trichlorophenol (0.046), i.e., 47-fold. Furthermore, the relative contribution of wax to phenanthrene sorption is up to 52.97% (Li and Chen, 2009), which is two-fold higher than that of 2,4,6-trichlorophenol (24.5%). This is a good evidence to demonstrate that polar group of chlorophenols can heavily depress the strong hydrophobic affinity of waxes. Sorption coefficients of chlorophenols all slightly increased after waxes removal, i.e., both $K_{d(AC2)}/K_{d(AC1)}$ and $K_{d(AC5)}/K_{d(AC6)} > 1$ (Table 5), indicating that waxes were not the major sorption medium for polar organic pollutants to the bulk plant cuticles.

The absence of cutin monomer decreased the K_d value (i.e., $K_{d(AC3)}/K_{d(AC2)}$, $K_{d(AC4)}/K_{d(AC5)} < 1$, Table 5), demonstrating that cutin component was a powerful sorption medium for polar organic pollutants. Moreover, the drop

Cutin	AC3/AC2	0.20	0.06	0.02	Sugar and cutan
	AC4/AC5	0.51	0.36	0.17	Cutan

Table 6 Relative contribution of waxes, cutin, and cutan to the sorption of chlorophenols by bulk apple cuticles

Sorbate	K_d (L/kg) ^a	RC ^b _{waxes} (%)	RC ^b _{cutin} (%)	RC ^b _{cutan} (%)	RC ^b _{sugar} (%)	Σ^c RC (%)
4-Chlorophenol	124±4.0	17.4	79.3	3.6	4.4	105
2,4-Dichlorophenol	400±9.8	18.1	88.6	2.7	1.5	111
2,4,6-Trichlorophenol	787±32.6	24.5	110.5	2.2	0.7	138

^a Sorption coefficients ($K_d = Q/C_e$) were calculated from experimental isotherms of bulk apple cuticle; ^b the relative contribution (RC) of each component was calculated by the ratio of the $f_i K_{d,i}$ to K_d of bulk cuticle. The symbol of i represents wax, cutin, cutan and sugar; f_i is the percentage of i component in bulk apple cuticle (Table 2); $K_{d,i}$ is the sorption coefficient of i component; ^c Σ RC is the sum of RC of waxes, cutin, cutan and sugar.

was dependent on the K_{ow} values of sorbates, i.e., the higher K_{ow} the bigger fall with the absence of cutin (Table 5). For example, K_d values of dewaxed apple cuticle (AC2) decreased 5, 17 and 50 times after alkaline saponification, i.e., $K_{d(AC3)}/K_{d(AC2)} = 0.20, 0.06$ and 0.02 for 4-chlorophenol, 2,4-dichlorophenol and 2,4,6-trichlorophenol, respectively. This was attributed to the hydrophobic rubbery nature of cutin fractions, producing high affinity for lipophilic sorbates (Shechter and Chefetz, 2008). To assess the relative contribution of cutin, sorption coefficients (K_d) of cutin was estimated through mass balance, i.e., $K_{d,AC2} \times f_2 = K_{d,AC3} \times f_3 + K_{d,cutin} \times f_{cutin}$, where f_2, f_3 , and f_{cutin} are the corresponding mass contents of AC2, AC3 and cutin in the bulk apple cuticle (Li and Chen, 2009). The respective calculated K_d of cutin were 244, 879 and 2158 L/kg for 4-chlorophenol, 2,4-dichlorophenol and 2,4,6-trichlorophenol. Correspondingly, their relative contribution of cutin was 79.3%, 88.6% and 110.5%, which were much higher than that of the other cuticular components.

Cutan (AC4) showed the most nonlinear isotherms for the stronger π - π bonding interaction (Table 4). With the increase in K_{ow} of sorbates, the nonlinearity raised due to the increasing π^* parameter (Table 1) (Li et al., 2010), and the sorption coefficients of cutan (AC4) were also enhanced, i.e., $K_{oc} = 129, 315$ and 511 L/kg for 4-chlorophenol, 2,4-dichlorophenol and 2,4,6-trichlorophenol, respectively. These values were similar to the sorption coefficients of polar sorbates with K_{ow} values of 257–501 onto pure cutan of *A. americana* leaves, i.e., $K_{oc} = 340, 110$ and 260 L/kg for atrazine, carbamazepine and chlorotoluron, respectively (Shechter and Chefetz, 2008). The lower sorption capacity of polar sorbates was attributed to the polar adsorptive sites in cutan inaccessible for sorption interactions. In comparison, cutan exhibited powerful sorption capability for nonpolar organic pollutants (i.e., phenanthrene and naphthalene), but the relative role of cutan depended upon whether the sugar component existed or not. With the coexistence of sugar, the sorption of cutan was completely suppressed.

Hence, for nonpolar organic pollutants, sorption coefficients of cutan were usually much higher than that of AC3 (e.g., $AC4/AC3 = 11$ for phenanthrene). However, the enhancement in K_d was smaller for 4-chlorophenol after acid hydrolysis ($K_{d(AC4)}/K_{d(AC3)} = 2.15$), indicating that the suppression effect of sugar was not so heavily when the sorbates were polar organic pollutant (Table 5). Moreover, such suppression effect became more and more distinctively with sorbate's K_{ow} increasing, supported by the higher enhancement of K_d values after acid hydrolysis, i.e., $K_{d(AC4)}/K_{d(AC3)} = 4.85$ for 2,4-dichlorophenol and 8.78 for 2,4,6-trichlorophenol. Despite the slighter suppression effect, the relative contribution of cutan to total sorption of bulk cuticle was very small (2.2%–3.6%) for the selected chlorophenols, which was similar to the contribution of cutan to phenanthrene sorption (2.84%).

The affinity of sugar with chlorophenols was the poorest in comparison with other components. Interestingly, the K_d values of 4-chlorophenol, 2,4-dichlorophenol and 2,4,6-trichlorophenol with AC3 were 33.7, 36.5 and 32.7 L/kg, respectively, which were quite similar. According to Table 2, the main composition of AC3 was cutan (27%) and sugar (73%). Since the sorption capacity of cutan was powerful and increased with the increase of sorbate's K_{ow} , sorption capacity of AC3 was expected to correspondingly rise. The almost constant K_d values of AC3 indicated that cutan in AC3 were unavailable to sorbates. Sorption of AC3 mainly was contributed from sugar, and the sorption capacity of sugar was similar for the selected chlorophenols because the sorption process was specific interactions (such as dipole-dipole and ion-dipole interaction) rather than hydrophobic interaction.

The relative roles of sugar to sorption of chlorophenols were sorbate-dependent. K_d value of 2,4,6-trichlorophenol increased after sugar removal, i.e., $K_{d(AC6)}/K_{d(AC1)} = 1.51$ and $K_{d(AC5)}/K_{d(AC2)} = 1.19$, consistent with previous reports (Chen et al., 2005). Nevertheless, the K_d values for 4-chlorophenol and 2,4-dichlorophenol decreased after acid hydrolysis ($K_{d(AC6)}/K_{d(AC1)}$ and $K_{d(AC5)}/K_{d(AC2)} < 1$, Table 6). Chen et al. (2005) observed a similar phenomena,

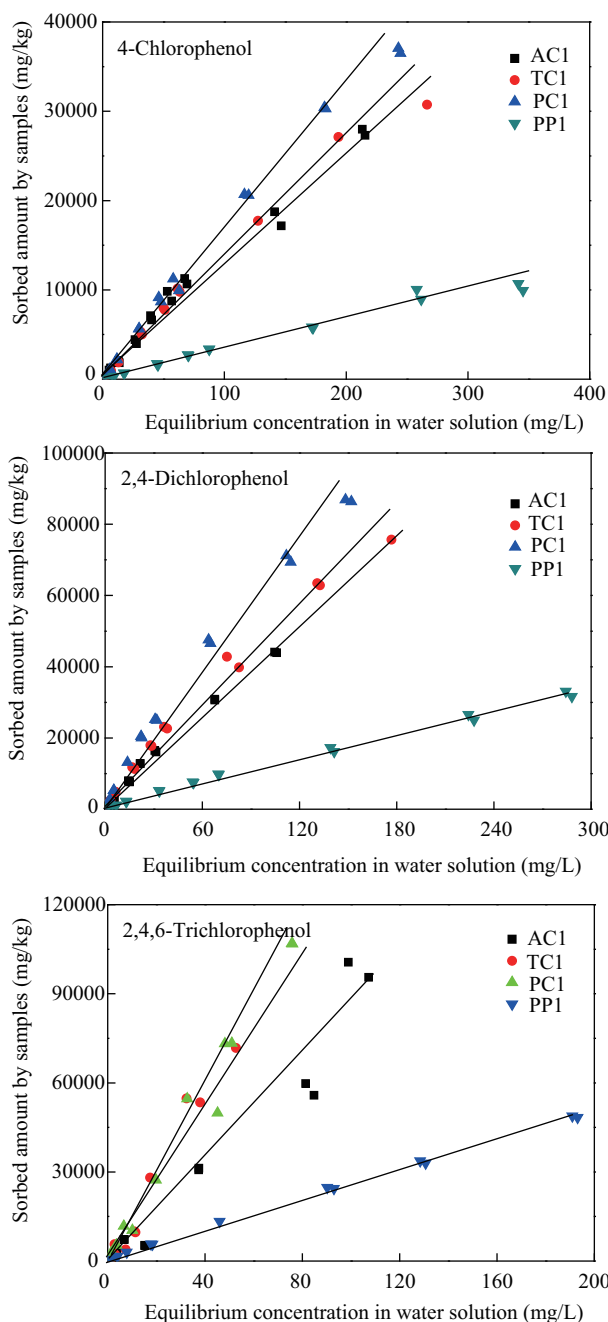

Fig. 1 Sorption isotherms of 4-chlorophenol, 2,4-dichlorophenol, and 2,4,6-trichlorophenol onto fruit cuticles and periderm. AC1: bulk apple cuticle; TC1: bulk tomato cuticle; PC1: bulk pepper cuticle; PP1: bulk potato periderm.

i.e., sorption affinity of 1-naphthol on pepper cuticle decreased after sugar removal ($K_{d(AC5)}/K_{d(AC2)} < 1$). In these cases, sugar did not play a negative role anymore and presented as an effective sorption medium, with relative contribution of 4.4% and 1.5% for 4-chlorophenol and 2,4-dichlorophenol, respectively (Table 6).

Note that, the sum of relative contribution was up to 100%, meaning that suppression effects between different cuticular components on sorption existed. This effect became stronger with K_{ow} increasing, supported by the increasing total RC of sorption from 105% for 4-chlorophenol to 138% for 2,4,6-trichlorophenol. With the increase of sorbate's K_{ow} , the K_{oc}/K_{owc} ratios for all

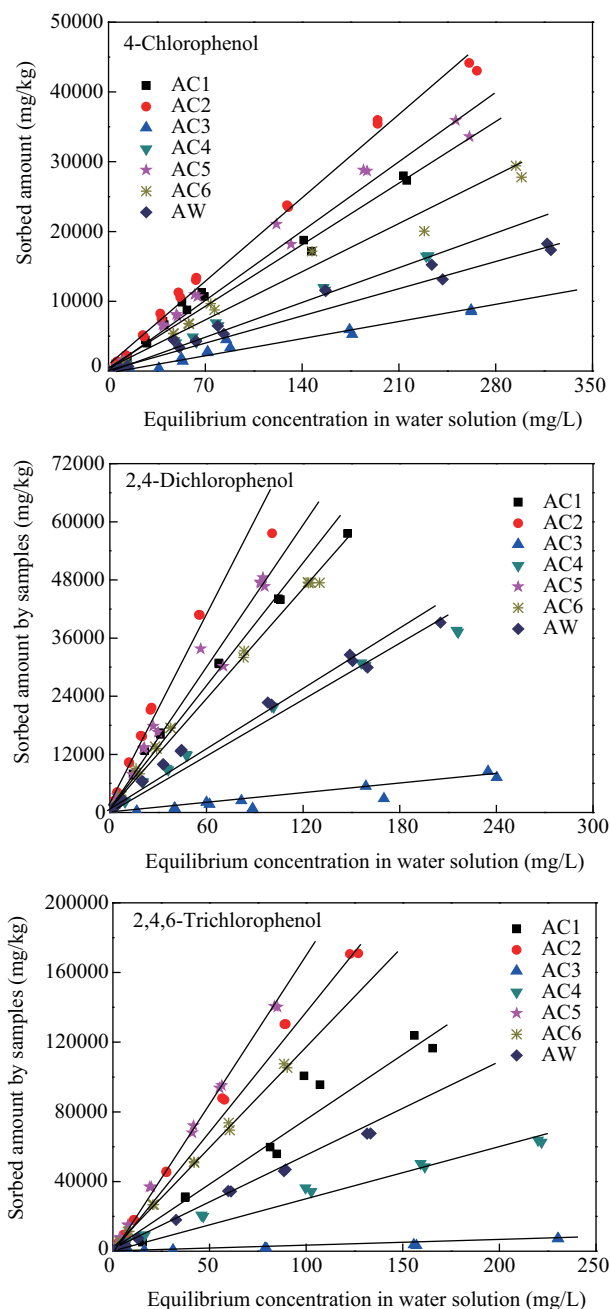

Fig. 2 Sorption isotherms of 4-chlorophenol, 2,4-dichlorophenol, and 2,4,6-trichlorophenol onto apple cuticular fractions.

cuticular fractions decreased. Positive correlation of the decreasing degree of K_{oc}/K_{owc} ratios with the sorbents' polarities is observed. For AC3 with highest polarity (Table 2), the K_{oc}/K_{owc} ratios of 2,4,6-trichlorophenol was 44 times lower than 4-chlorophenol, which may be attributed to the higher suppression effect contributed by the higher polarity of sorbents.

In summary, cutin and waxes are the major sorption medium of apple bulk cuticle with chlorophenols, and the dominant sorption mechanism is hydrophobic interactions. The ratios of K_{oc}/K_{owc} decrease for the increasing degree of ionization of the sorbates. Sorption capacity of plant cuticle/periderm samples increases with increasing sorbate's K_{ow} (except AC3). The polarity rooting from sorbents and sorbates could restrict hydrophobic interactions, and the

K_{oc}/K_{owc} ratios decrease with the increase of sorbates' K_{ow} . The relative contribution of each cuticular component is in an order of cutin > waxes > sugar (cutan). With the increase of K_{ow} values, the relative contribution of lipophilic components (wax, cutin and cutan) on sorption increases, whereas the contribution of polar sugar decreases.
