**Abstract:** A new method, without assistance of activity ratio diagram, was applied to construct the  $p\epsilon$ -pH diagrams for chlorine system. The optimal pH range for generation of  $\text{ClO}_2$  by contacting  $\text{Cl}_2(\text{g})$  directly with  $\text{ClO}_2^-$  solution is within pH 1.35—1.94, particularly within pH 1.35—4.00 only if minimizing the formation of  $\text{Cl}_2$ . It is unachievable to synthesize pure  $\text{ClO}_2$  from the reaction of  $\text{Cl}_2$  and  $\text{ClO}_2^-$ . Conversely,  $\text{ClO}_2$  may be present a variation of stability in different waters owing to the changed  $p\epsilon$  and pH.  $\text{ClO}_2$  could be relatively stable if not disproportionate into  $\text{ClO}_3^-$ , coexisting with  $\text{ClO}_2^-$  ( $p\epsilon$  17.63 and  $\text{pH} > 9.68$ ),  $\text{Cl}_2$  ( $\text{pH} \leq 0.92$ ) or  $\text{Cl}^-$  ( $\text{pH} 0.92$ —9.68). When chlorine system has already reached the ultimate equilibria,  $\text{ClO}_2$  is a stable species in strongly acid media. As the acidity decreases,  $\text{ClO}_2$  disproportionates into  $\text{ClO}_3^-$  and  $\text{Cl}_2$ . Aqueous  $\text{ClO}_2$  is unstable within the normal pH range. This work initially, theoretically elucidates the generation and stability of  $\text{ClO}_2$  by way of the  $p\epsilon$ -pH diagrams.

**Keywords:** chlorine dioxide; generation; stability;  $p\epsilon$ -pH diagram

## Introduction

Due to the formation of some potentially hazardous by-products from chlorine disinfection in drinking water, chlorine dioxide ( $\text{ClO}_2$ ), as an alternative disinfectant and an effective oxidant, formed fewer halogenated DBPs than chlorine (Richardson, 1994; 2000; Bryant, 1992). Investigations of the generation and stability of  $\text{ClO}_2$  have already promoted its application. However, previous studies pay no attention to the factor of electron activity ( $p\epsilon$ ) that actually affects the generation and stability of  $\text{ClO}_2$ . The ignorance of  $p\epsilon$  appearance, particularly the combined effects of  $p\epsilon$  and pH, has restricted the application of  $\text{ClO}_2$  to a certain degree. This paper discusses the generation and stability of  $\text{ClO}_2$  by way of  $p\epsilon$ -pH diagrams, which enrich the chemistry of  $\text{ClO}_2$ , as well as particularly enhance the knowledge of chemist to characteristics of  $\text{ClO}_2$  and improve the application of  $\text{ClO}_2$  in water treatment.

A great number of methods for synthesis of  $\text{ClO}_2$  are valid from  $\text{ClO}_2^-$  and  $\text{ClO}_3^-$ .  $\text{ClO}_2$  may be produced in large quantities by acidifying and reducing  $\text{ClO}_3^-$  while many generation techniques is mainly focus on the reaction of  $\text{Cl}_2$  and  $\text{ClO}_2^-$ . Moreover,  $\text{ClO}_2$  is normally stored in aqueous solution with pH 2—3, protection against light (Richardson, 1994; 2000). A stabilized  $\text{ClO}_2$  solution might be obtained at pH 6—8 by passing gaseous  $\text{ClO}_2$  into an aqueous solution containing 12% sodium carbonate and hydrogen peroxide, yet  $\text{ClO}_2$  is practically completely transited to  $\text{ClO}_2^-$  in this method, thus the reduction of  $\text{ClO}_2$  to  $\text{ClO}_2^-$  may be partly interpreted as the storage technique for  $\text{ClO}_2$  (Richardson, 1994; 2000).

The literature contains controversy as to whether or not  $\text{ClO}_2$  is stable in aqueous solution. On one hand, aqueous solutions of  $\text{ClO}_2$  were quite stable if kept cool, well sealed, and protected from light.  $\text{ClO}_2$  was less sensitive to change in pH, and the stability of  $\text{ClO}_2$  is between that of  $\text{Cl}_2$  and ozone (Richardson, 1994). Some observations are on the other hand quite the reverse.  $\text{ClO}_3^-$  may be present as a disproportionate reaction product in measurable quantities in chlorinated drinking water, depending on the applied  $\text{ClO}_2$  dosage (Richardson, 1994). Because  $\text{ClO}_2$  reacts primarily by a one-electron oxidative pathway, so the principal inorganic by-product is almost invariably  $\text{ClO}_2^-$ .  $\text{ClO}_2$  also decomposes into  $\text{Cl}_2$

and  $O_2$  once the temperature has reached  $15^\circ\text{C}$  (Richardson, 2000).  $OCl^-$  has been known to cause  $ClO_2$  losses in moderately basic media (Richardson, 2000). Aqueous solution of  $ClO_2$  certainly contains  $Cl^-$  (Yin, 1998; Ni, 1997). Different scientists recognized the stability of  $ClO_2$  from their specific experiments, thus the recognitions is diversified. No united theoretical explanation is so far satisfactorily accepted.

## 1 Method

The traditional method for constructing a  $p\epsilon$ -pH diagram usually needs to construct an activity ratio diagram either at a given  $p\epsilon$  or at a given pH, which may clarify the stability relations if any doubt should arise about which species predominates thermodynamically (Richardson, 2000). Excessive work is apparently taken when adopting the traditional method. We suggest a new method constructing the  $p\epsilon$ -pH diagrams based on the equilibria of tri-oxychlorine species. The method excludes the construction of activity ratio diagram and simplifies the construction of  $p\epsilon$ -pH diagram.

Consider oxychlorine species A, B and C, the oxidization states decrease sequentially. For any tri-oxychlorine species, only four kinds of equilibria among species A, B and C are summarized in Fig. 1. For instance,  $ClO_3^-$ ,  $ClO_2$  and  $Cl_2$  satisfy the diagram in Fig. 1a;  $ClO_2$ ,  $ClO_2^-$  and  $Cl^-$  fit within the diagram in Fig. 1b;  $HClO_2$ ,  $HOCl$  and  $Cl_2$  match the diagram in Fig. 1c; and compared with  $ClO_2$  and  $Cl_2$ , no predominance area for  $HClO_2$  can exist, which satisfy the diagram in Fig. 1d.

Fig. 1  $p\epsilon$ -pH diagrams of tri-species equilibria

Derived from the basic diagrams above, the  $p\epsilon$ -pH diagrams for chlorine system with multi-oxychlorine species may be established gradually. The  $p\epsilon$ -pH diagram for chlorine system with  $HOCl$ ,  $OCl^-$ ,  $Cl_2$  and  $Cl^-$  may be found in the literature (Richardson, 1994; 2000; Aieta, 1986a). This work has further established three  $p\epsilon$ -pH diagrams for chlorine system with six, seven and eight oxychlorine species based on the equilibria of tri-oxychlorine species, respectively. In the diagrams, unit concentration ratios for oxidants and reductants are considered on the boundaries. The new method has overcome the shortcoming of the traditional method, thus it is simpler and more convenient than the traditional method.

## 2 Results and discussion

Three  $p\epsilon$ -pH diagrams, in which the highest oxidation states are III ( $HClO_2$ ), IV ( $ClO_2$ ) and V ( $ClO_3^-$ ), have been established to analyze the generation and stability of  $ClO_2$ .

Fig. 2 shows the  $p\epsilon$ -pH diagram for chlorine system with  $HClO_2$ ,  $ClO_2^-$ ,  $HOCl$ ,  $OCl^-$ ,  $Cl_2$  and  $Cl^-$  (298 K,  $1.013 \times 10^5$  Pa). The total dissolved chlorine ( $C_{T,Cl}$ ) is 0.03 mol/L. No predominance area for  $OCl^-$  is found in the diagram, which illustrates that  $OCl^-$  was unstable and transited to other oxychlorine species before the equilibria have been reached. In the diagram, seven  $p\epsilon$ -pH equations (Table 1) contribute to as many boundaries. The redox stability of water is in the area between two dot lines whose  $p\epsilon$ -pH equations are listed in Table 1.

Fig. 2  $p\epsilon$ -pH diagram for the chlorine system with  $HClO_2$ ,  $ClO_2^-$ ,  $HOCl$ ,  $OCl^-$ ,  $Cl_2$  (aq) and  $Cl^-$  (298K,  $1.013 \times 10^5$  Pa,  $C_{T,Cl} = 0.03$  mol/L.)

The  $p\epsilon$ -pH diagram for chlorine system with  $\text{ClO}_2$ ,  $\text{HClO}_2$ ,  $\text{ClO}_2^-$ ,  $\text{HOCl}$ ,  $\text{OCl}^-$ ,  $\text{Cl}_2$  and  $\text{Cl}^-$  (298 K,  $1.013 \times 10^5$  Pa,  $C_{\text{T,Cl}} = 0.03$  mol/L) is shown in Fig. 3. In the diagram,  $\text{HClO}_2$ ,  $\text{HOCl}$  and  $\text{OCl}^-$  are unstable. Five  $p\epsilon$ -pH equations (Table 1) are corresponding to the boundaries. Fig. 4 shows the  $p\epsilon$ -pH diagram for chlorine system with  $\text{ClO}_3^-$ ,  $\text{ClO}_2$ ,  $\text{HClO}_2$ ,  $\text{ClO}_2^-$ ,  $\text{HOCl}$ ,  $\text{OCl}^-$ ,  $\text{Cl}_2$  and  $\text{Cl}^-$  (298 K,  $1.013 \times 10^5$  Pa,  $C_{\text{T,Cl}} = 0.03$  mol/L). In the diagram  $\text{HClO}_2$ ,  $\text{ClO}_2^-$ ,  $\text{HOCl}$ , and  $\text{OCl}^-$  had almost been transited to  $\text{ClO}_3^-$ ,  $\text{ClO}_2$ ,  $\text{Cl}_2$  and  $\text{Cl}^-$  before the equilibria were reached. Because the formation of  $\text{ClO}_2^-$  is always observed in waters, chlorine system is in fact far from the ultimate equilibria. Five  $p\epsilon$ -pH equations (Table 1) contribute to the boundaries in the diagram.

## 2.1 Generation of chlorine dioxide

In Fig. 2, no coexisting boundary is presented between  $\text{Cl}_2$  and  $\text{ClO}_2^-$ , thus  $\text{Cl}_2$  reacts with  $\text{ClO}_2^-$  if they contact. On site, it is common to generate  $\text{ClO}_2$  from the reaction of  $\text{Cl}_2$  and  $\text{NaClO}_2$ . According to the diagram, by-products are certainly produced in the generation process because  $\text{Cl}_2$  may disproportionate into  $\text{HOCl}$ , further into  $\text{ClO}_2^-$  and  $\text{Cl}^-$ , which agrees

**Table 1** The  $p\epsilon$ -pH equations reflected to the boundaries in Fig. 2, Fig. 3 and Fig. 4 (298 K,  $1.013 \times 10^5$  Pa,  $C_{\text{T,Cl}} = 0.03$  mol/L)

No.	$p\epsilon$ -pH equations	Standard electron activity, $p\epsilon^\circ$	Boundaries
1	$p\epsilon = 24.64^a$	23.64	$\text{Cl}_2$ - $\text{Cl}^-$
2	$p\epsilon = 27.31 - \text{pH}$	27.31	$\text{ClO}_2^-$ - $\text{Cl}^-$
3	$p\epsilon = 28.32 - \text{pH}$	28.32	$\text{HClO}_2$ - $\text{HOCl}$
4	$p\epsilon = 25.99 - \text{pH}^a$	26.99	$\text{HOCl}$ - $\text{Cl}_2$
5	$\text{pH} = 1.94$		$\text{HClO}_2$ - $\text{ClO}_2^-$
6	$p\epsilon = 29.31 - 1.5\text{pH}$	29.31	$\text{ClO}_2$ - $\text{HOCl}$
7	$p\epsilon = 25.31 - 0.5\text{pH}$	25.31	$\text{HOCl}$ - $\text{Cl}^-$

12	$p\epsilon = 24.53 - 1.2\text{pH}^a$	24.73	$\text{ClO}_3^-$ - $\text{Cl}_2$
13	$p\epsilon = 24.55 - \text{pH}$	24.55	$\text{ClO}_3^-$ - $\text{Cl}^-$
14	$p\epsilon = 20.6 - \text{pH}$	20.6	$\text{O}_2$ - $\text{H}_2\text{O}$
15	$p\epsilon = -\text{pH}$	0	$\text{H}_2\text{O}$ - $\text{H}_2$

Notes: <sup>a</sup> The first coefficient in the equation is different from the standard electron activity ( $p\epsilon^\circ$ ) because the coefficient is related to the concentrations of oxychlorine species (Yen, 1999)). The boundaries in Fig. 2 are drawn by Equations (1)–(7). The boundaries in Fig. 3 are drawn by Equations (1), (2), (8)–(10). The boundaries in Fig. 4 are drawn by Equations (1), (8), (11)–(13). Equations (14) and (15) describe the boundaries of  $\text{O}_2$ - $\text{H}_2\text{O}$  and  $\text{H}_2\text{O}$ - $\text{H}_2$ , respectively.

Fig. 3  $p\epsilon$ -pH diagram for the chlorine system with  $\text{ClO}_2$ ,  $\text{HClO}_2$ ,  $\text{ClO}_2^-$ ,  $\text{HOCl}$ ,  $\text{OCl}^-$ ,  $\text{Cl}_2$  (aq) and  $\text{Cl}^-$  (298K,  $1.013 \times 10^5$  Pa,  $C_{\text{T,Cl}} = 0.03$  mol/L)

Fig. 4  $p\epsilon$ -pH diagram for the chlorine system with  $\text{ClO}_3^-$ ,  $\text{ClO}_2$ ,  $\text{HClO}_2$ ,  $\text{ClO}_2^-$ ,  $\text{HOCl}$ ,  $\text{OCl}^-$ ,  $\text{Cl}_2$  (aq) and  $\text{Cl}^-$  (298K,  $1.013 \times 10^5$  Pa,  $C_{\text{T,Cl}} = 0.03$  mol/L)

to the experimental observation (Richardson, 2000). If adopting the reaction of contacting  $\text{Cl}_2(\text{g})$  directly with  $\text{ClO}_2^-$  solution to generate  $\text{ClO}_2$ , the more optimal pH range is within pH 1.35—1.94. Only for minimizing the formation of  $\text{Cl}_2$ , without consideration of  $\text{ClO}_2^-$ , the pH range may enlarge to pH 1.35—4.00. In practice, if the  $p\epsilon$  is suitably controlled, highly pure  $\text{ClO}_2$  can be produced within pH 2—3 (Aieta, 1986b) and pH 3—4 (Lauer, 1986). However, it is indeed unachievable to generate pure  $\text{ClO}_2$ .

Similar to even clearer than Fig. 2, Fig. 3 shows that,  $\text{Cl}_2$  and  $\text{ClO}_2^-$  are stable under different pH and  $p\epsilon$  ranges. The redox reaction of  $\text{Cl}_2$  and  $\text{ClO}_2^-$  produces  $\text{ClO}_2$  and releases  $\text{Cl}^-$ . Upon introduction of acid into a  $\text{ClO}_2^-$  solution, the equilibrium shifts toward left along the half dash-dot line 1 ( $L_1$ , “L” represents the half dash-dot line, and the subscription “1” represents the serial number), thus  $\text{ClO}_2$  and  $\text{Cl}^-$  may be produced from  $\text{ClO}_2^-$ . Then  $\text{Cl}^-$  is however more predominant than  $\text{ClO}_2$ . The acidification of  $\text{ClO}_2^-$  solution might have been a way of the generation of  $\text{ClO}_2$ , yet this method cannot produce  $\text{ClO}_2$  well because of the presence of rather excessive  $\text{Cl}^-$ . Likewise, if pH is held as a constant and  $p\epsilon$  grows along  $L_2$ ,  $\text{ClO}_2^-$  will be oxidized to  $\text{ClO}_2$ . Electrolytic route may produce  $\text{ClO}_2$  from  $\text{ClO}_2^-$  solution. Actually, generation of  $\text{ClO}_2$  from  $\text{ClO}_2^-$  involves the combined process of acidification and oxidization. As shown in Fig. 4, it is also feasible to synthesize  $\text{ClO}_2$  from  $\text{ClO}_3^-$ . The processes of acidifying ( $L_1$ ) and reducing ( $L_2$ )  $\text{ClO}_3^-$  may produce  $\text{ClO}_2$ , which two processes function together in practice.

Generation of  $\text{ClO}_2$  through the processes of acidification, oxidization and reduction embodies as the change of  $p\epsilon$  and pH in the diagrams. As a result, the generation of  $\text{ClO}_2$  is in fact to shift the equilibria of chlorine system into the predominance area of  $\text{ClO}_2$ .

## 2.2 Stability of chlorine dioxide

As indicated in Fig. 3, the oxidizing power of  $\text{ClO}_2$  is stronger than that of  $\text{O}_2$ , thus  $\text{ClO}_2$  may oxidize  $\text{H}_2\text{O}$ , releasing  $\text{O}_2$ .  $\text{ClO}_2$  exists above the stable areas of  $\text{Cl}_2$ ,  $\text{Cl}^-$  and  $\text{ClO}_2^-$ , thus  $\text{ClO}_2$  can steadily coexist with them on the boundaries. When pH is less than 0.92,  $\text{ClO}_2$  can coexist with  $\text{Cl}_2$ , which maybe explain the phenomenon of  $\text{Cl}_2(\text{g})$  releasing from  $\text{ClO}_2$  solution (Griese, 1992). As  $\text{ClO}_2$  concentration decreased,  $\text{ClO}_2^-$  concentration generally increased (Richardson, 2000). According to the diagram,  $\text{ClO}_2$  has the same concentrations with  $\text{ClO}_2^-$  at  $p\epsilon$  17.63 when pH is higher than 9.68.  $\text{ClO}_2$  also coexists with  $\text{Cl}^-$  within pH 0.92—9.68, which approves that aqueous solution of  $\text{ClO}_2$  certainly contains  $\text{Cl}^-$  (Yin, 1998; Ni, 1997).

Fig. 3 shows that  $\text{ClO}_2$  may decrease its stability and transit to  $\text{Cl}^-$  ( $L_3$ ,  $L_4$ ,  $L_8$  or  $L_9$ ),  $\text{Cl}_2$  ( $L_7$  or  $L_8$ ) and  $\text{ClO}_2^-$  ( $L_9$ ) by the variation of  $p\epsilon$  and pH.  $\text{ClO}_2$  may tend to be much stable when the number of protons or electrons decreases ( $L_5$  or  $L_6$ ). Apparently, the experimental observation does not satisfy the conclusion of which  $\text{ClO}_2$  favors alkaline solution. Further discussions are addressed next.

In Fig. 3, the disproportionation of  $\text{ClO}_2$  has been not considered. The ultimate equilibria of chlorine system including the disproportionation of  $\text{ClO}_2$  are shown in Fig. 4, which reflects the stability of  $\text{ClO}_2$  absolutely.  $\text{ClO}_2$  may transit to  $\text{Cl}_2$  ( $L_3$  or  $L_4$ ),  $\text{Cl}^-$  ( $L_4$ ) and  $\text{ClO}_3^-$  ( $L_5$  or  $L_6$ ) by the variation of  $p\epsilon$  and pH. In Fig. 4,  $\text{ClO}_2$  is only a stable species in strongly acid media, and disproportionates into  $\text{ClO}_3^-$  and  $\text{Cl}_2$  when the acidity decreases. Thus  $\text{ClO}_2$  cannot steadily exist within the normal pH range. In addition, the lower boundary of the predominance area of  $\text{ClO}_2$  parallels to the upper boundary of that of  $\text{H}_2\text{O}$  in Fig. 4 (also Fig. 3), no coexisting area both for  $\text{ClO}_2$  and  $\text{H}_2\text{O}$ , thus aqueous  $\text{ClO}_2$  cannot steadily exist even in strongly acid media.

As described above (see Introduction), there appears controversy as to whether or not  $\text{ClO}_2$  is stable in aqueous solution. The actual stability of  $\text{ClO}_2$  should be essentially between the descriptions of the

diagrams in Fig. 3 and Fig. 4. The  $p_e$  and pH may control the disproportionation of  $\text{ClO}_2$  and equilibria of chlorine system.  $\text{ClO}_2$  consequently expresses itself completely dissimilar stabilities under different conditions in waters. Therefore, the  $p_e$  and pH should be the principal factors when evaluating the stability of  $\text{ClO}_2$ .

### 3 Conclusions

Generation, storage, and use of  $\text{ClO}_2$  have a strong relationship with the stability of aqueous  $\text{ClO}_2$ . It is unachievable to synthesize pure  $\text{ClO}_2$  from the reaction of  $\text{Cl}_2$  and  $\text{ClO}_2^-$ .  $\text{ClO}_2$  may be present a variation of stability in different waters owing to the changed  $p_e$  and pH.  $\text{ClO}_2$  could be relatively stable if not disproportionate into  $\text{ClO}_3^-$ . When the ultimate equilibria of chlorine system have been achieved,  $\text{ClO}_2$  is a stable species in strongly acid media. Aqueous  $\text{ClO}_2$  is unstable within the normal pH range.
