ABSTRACT

The ozonolysis of 2,3,7,8-tetra-chlorodibenzo-p-dioxin (2,3,7,8-TCDD) is an efficient degradation way in the atmosphere. The ozonolysis process and possible reactions path of Criegee Intermediates with NO and H₂O are introduced in detail at the method of MPWB1K/6-31+G(d,p)//MPWB1K/6-311+G(3df,2p) level. In ozonolysis, H₂O is an important source of OH radical formation and initiated the subsequent degradation reaction. The Rice-Ramsperger-Kassel-Marcus (RRKM) theory was applied to calculate rate constants with the temperature ranging from 200 to 600 K. The rate constant of reaction between 2,3,7,8-TCDD and O₃ is $4.80 \times 10^{-20} \text{ cm}^3/(\text{mole} \cdot \text{sec})$ at 298 K and 760 Torr. The atmospheric lifetime of the reaction species was estimated according to rate constants, which is helpful for the atmospheric model study on the degradation and risk assessment of dioxin.

Introduction

With the increasing of environmental awareness, the persistent organic pollutants (POPs) have leaped into people's view. As typical POPs, dioxins with the carcinogenic, teratogenic, and mutagenic effects (Schechter, 1994), are a class of structurally and chemically related polyhalogenated aromatic hydrocarbons that mainly include polychlorinated dibenzo-p-dioxins (PCDDs) and dibenzofurans (PCDFs) (Schechter et al., 2006; Kulkarni et al., 2008). PCDD/Fs are mainly emitted to the atmosphere from incineration, combustion, industrial and reservoir sources (Lin et al., 2008; Chiu et al., 2011). Chi et al. (2007, 2009) studied the historical trends of PCDD/Fs in sediments buried in a reservoir and measured atmospheric deposition by automated and traditional samplers in Northern Taiwan. Because of their biological

effects and high toxicities, the investigation of dioxin's destruction is of great significance. To destroy these recalcitrant compounds, a growing interest has been provoked in developing efficient and economically feasible remediation technologies including incineration and thermal treatment (Weber et al., 1999; Lundin and Marklund, 2005), catalytic destruction (Ide et al., 1996; Debecker et al., 2011), photocatalysis (Choi et al., 2000), photolysis (Konstantinov et al., 2000; Rayne et al., 2002; Choi et al., 2004), radiolysis (Hilaridles et al., 1994), ozonolysis (Vollmuth and Niessner, 1995) and biodegradation (Mori and Kondo, 2002; Fennell et al., 2004). However, most of these methods are not suitable for the degradation of PCDD/Fs in the atmosphere. Gaseous PCDD/Fs are primarily depleted when reacting with OH, NO₃ radicals and O₃ in the atmosphere (Kwok and Atkinson, 1995; Atkinson, 1996). All of those oxidants play an important role in the atmospheric chemistry. The reaction of gaseous PCDD/Fs congener with OH is reported to be at least 8 and 3 orders of magnitude faster than their reactions with

* Corresponding author. E-mail: sxmwch@sdu.edu.cn

O₃ and NO₃ radicals (Atkinson, 1996). And the OH and O₃ concentration in atmosphere are 2.0×10^6 mole/cm³ and 7.0×10^{11} mole/cm³, respectively. Obviously the O₃ concentration is much higher than OH radical, thus the role of ozone can not be ignored in atmospheric environment. Furthermore, the main oxidants in the atmosphere are OH radical and O₃ during the daytime, while the main oxidants are NO₃ and O₃ at night. So the ozone takes effect all the time and it is a highly reactive gas with a strong oxidability, which can promote heterogeneous chemical reactions faster with the organic matters, especially those with double bonds in their chemical systems. Recently the investigation of O₃ has aroused considerable attention (José et al., 2005; Al-Alawi et al., 2008), and many experimental and theoretical studies of the ozonolysis reactions have been carried out. Most importantly, the ozone arises from a variety of resources, including anthropogenic sources and natural sources. Given that dioxin congeners share similar chemical and physical properties, 2,3,7,8-TCDD, the most toxic congener among all dioxin congeners (Schechter et al., 2006; Kulkarni et al., 2008), is selected as a typical one in this study.

Although the experiments of PCDD/Fs' ozonolysis have been performed, the reaction mechanism is still not clear. Recently, ab initio molecular orbital calculation is widely adopted to interpret experimental findings and to provide theoretical understanding for chemical transformation processes. Many theoretical studies on the formation of PCDD have been reported (León et al., 2002; Khachatryan et al., 2003; Fabian and Janoschek 2006; Altarawneh et al., 2007, 2008; Zhang et al., 2008, 2010; Qu et al., 2009; Xu et al., 2010, 2011; Yu et al., 2011). Therefore, invalidation of the degradation mechanism under different conditions is necessary. Zhang et al. (2011, 2012) used quantum chemical theory to clarify the mechanism for OH-initiated degradation of 2,3,7,8-TCDD and 2,3,7,8-TCDF in the presence of O₂ and NO/H₂O. Wen et al. (2010) reported a possible ozonolysis degradation mechanism of the 2,3,7,8-TCDD. But it can be found that Wen's research is only based on the stereoeffect, while the electronic effect is neglected. By means of thermodynamic and kinetic analysis, the two easiest pathways of the ozonolysis degradation over the low temperature range are given in this article. Some reactions of intermediates with NO and H₂O are also discussed. The rate constants are calculated and the atmospheric lifetime of the reaction species is estimated accordingly.

1 Computational method

1.1 Geometry optimization

The unrestricted MPWB1K method is used to treat systems with an even number of electrons but with partial open-

shell character, such as ozone, the Criegee biradicals. The MPWB1K method is a hybrid density functional theory model with excellent performance for thermochemistry, thermochemical kinetics, hydrogen bonding, and weak interactions. It is well-known that MPWB1K is an excellent method to predict transition state geometries and thermochemical kinetics, based on the modified Perdew and Wang exchange functional (MPW) and Becke's 1995 correlation functional (B95) (Zhao and Truhlar, 2004). MPWB1K method has ever been applied to the study of ozonolysis reactions (Yang et al., 2007, 2008). In all reaction channels, the geometry structures of various reactants, transition states, intermediates and products are optimized at the MPWB1K/6-31+G(d,p) level. The vibrational frequencies are also calculated at the same level to determine the nature of stationary points. The selection of basis set is important to get precise results (Zhang et al., 2000). The single-point energy calculations are performed at a higher level of theory MPWB1K/6-311+G(3df,2p). All the work is performed using the Gaussian 03 programs (Frisch et al., 2003) and SGI workstation.

1.2 Kinetic calculation

The initial information obtained from ab initio calculations allows us to calculate the rate constants. The kinetic calculations have been carried out using Rice-Ramsperger-Kassel-Marcus (RRKM) theory modified by Hou and Wang (2007). This method has been successfully used in the previous ozonolysis study (Wang et al., 2010; Sun et al., 2011).

2 Results and discussion

2.1 Ozonolysis reaction

Scheme 1 shows the structure of 2,3,7,8-TCDD. There are four different kinds of C=C double bonds labeled as A, B, C and D, respectively, which can be attacked by O₃. According to the stereoeffect, Wen et al. (2010) has reported that the D position is the most probable pathway for 2,3,7,8-TCDD to react with O₃. In fact, both the electronic effect and stereoeffect should be taken into consideration. The thermodynamic and kinetic calculations of the four positions with O₃ are performed. The potential energy surface is drawn in **Fig. 1**. Obviously, the barriers of path A (10.29 kcal/mol) and path B (9.79 kcal/mol) are lower than those of path C (14.51 kcal/mol) and path D (14.93 kcal/mol). Due to the distinction of calculation methods, the potential barrier of path D is different from the data (12.25 kcal/mol) of Wen et al. (2010).

The ozonolysis reaction is initiated by addition of ozone to the double bonds of 2,3,7,8-TCDD to produce a primary ozonide. The unstable five-membered ring of primary ozonide can easily break up in the the C–C bond and O–O

bonds part to generate a high-energy criegee intermediate and a relatively stable aldehyde or ketone. In this article, the four ozonolysis reactions are similar, but path A and B are chosen to discuss the mechanism since they take up the major proportion in most of the temperature range. The structures of all the reactants, intermediates, transition states and products are listed in **Fig. S3**.

2.1.1 Reaction channel A

The main possible reaction paths for the reaction of 2,3,7,8-TCDD with O_3 are listed in **Scheme 2**. Reaction channel A is the O_3 addition to the $>C2=C3<$ bond. Firstly, 2,3,7,8-TCDD reacts with O_3 via TSa1 to generate IMa1, with a potential barrier of 10.29 kcal/mol and the reaction heat of -36.80 kcal/mol. Then the C2–C3 and O1–O3 bonds of the five-membered ring in the IMa1 will be broken via TSa2 to form IMa2, the barrier is 25.30 kcal/mol and the reaction heat is -11.00 kcal/mol (**Fig. 2**). It can be seen that the IMa2 contains a benzene ring and two C=C double bonds. Obviously, the ozone can be added to the benzene ring or the C=C double bonds sequentially. With their barriers compared, the reaction $IMa2 + O_3 \rightarrow TSa32 \rightarrow IMa32$ is determined to be the most probable

Scheme 1 Structure of 2,3,7,8-TCDD.

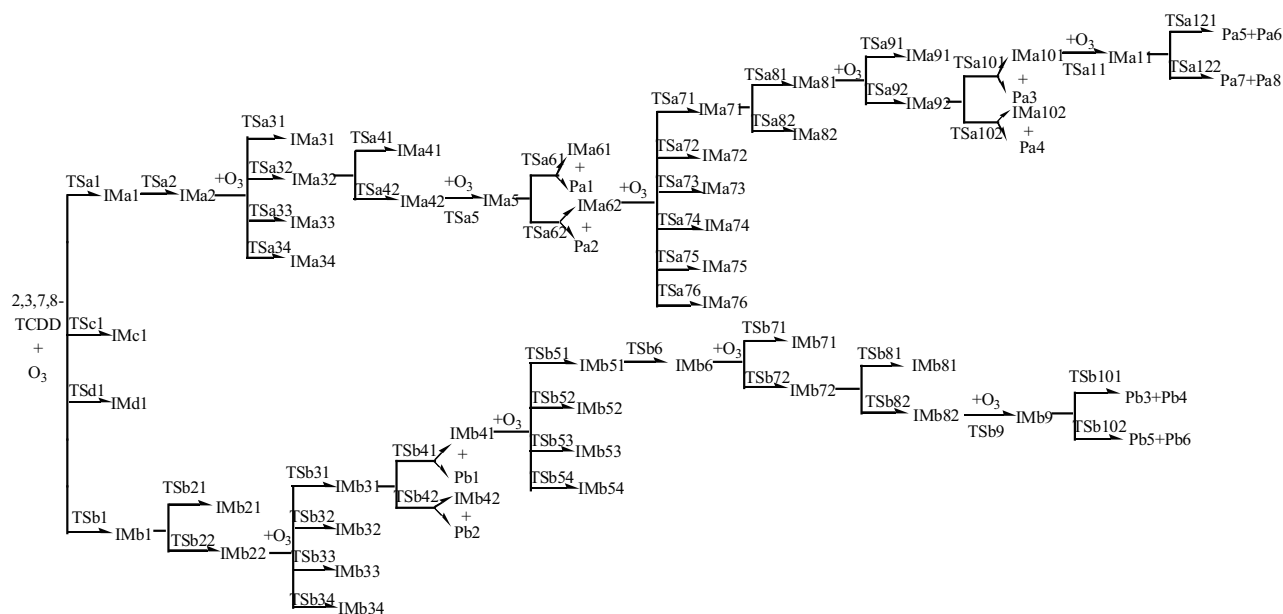

Fig. 1 Profile of potential energy ΔE surface for the first step reaction of 2,3,7,8-TCDD with O_3 .

reaction channel. The subsequent ozonolysis processes are similar to the above discussed and the whole reaction route is listed in the **Scheme 1** and the profile of potential energy surface for the subsequent reactions of reaction channel A is drawn in **Fig. S1**.

2.1.2 Reaction channel B

The reaction channel B is the O_3 addition to the $>C1=C2<$ which has the lowest potential barrier among the four channels. Firstly, the 2,3,7,8-TCDD reacts with O_3 to produce IMb1 via TSb1 with a potential barrier of 9.79 kcal/mol and a relative energy of -38.05 kcal/mol (**Fig. 1**). The asymmetric IMb1 is different from the symmetrical IMa1, so that the five-membered ring in IMb1 has two pathways to break and generate two intermediates, that is, IMb21 and IMb22, respectively. Similarly, IMb22 is chosen as the reactant in the subsequent reaction after

Fig. 2 Profile of potential energy surface for the Ima1 and the following reactions.

the potential barrier and relative energy are compared (**Fig. 3**). The ozonolysis reaction occurs unceasingly until the products do not contain double bonds any longer. The profile of potential energy surface for the subsequent reactions of reaction channel B is drawn in **Fig. S2**.

The ozonolysis reaction initiated by C or D position is similar to the reaction channel A and B discussed above.

According to many reported results, the unimolecular reactions such as isomerization are also very important. Consideration of the large system of reactants, the Ima2 and IMb22 are only chosen to study the mechanism of isomerization. The reaction path is described as follows:

From the values of reaction barrier, a conclusion can be drawn that the isomerization reactions are not easy to occur to intermediates which contain the benzene ring.

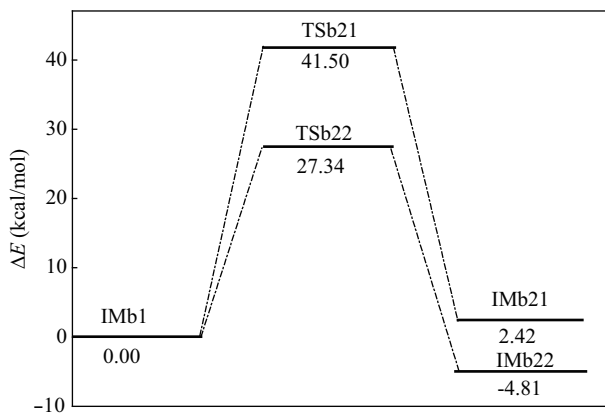

Fig. 3 Profile of potential energy surface for the IMb1.

2.2 Reactions in the presence of NO and H₂O

It should be pointed out that the ozonolysis reactions of 2,3,7,8-TCDD discussed above will occur only on the existence of ozone. It is well known that there are many abundant atmospheric precursors in the atmosphere, such as NO and H₂O. The criegee intermediates produced from the reaction of ozonolysis of 2,3,7,8-TCDD can react easily with these precursors. Some criegee intermediates in reaction channel A and B will be chosen as research object to discuss the reaction mechanism with NO and H₂O.

2.2.1 Reaction of Ima2

In the reaction channel A, the first criegee intermediate is Ima2. The profiles of the potential energy surface of Ima2 with NO and H₂O are drawn in **Fig. 4**. The potential barrier and exothermic energy for the process of Ima2 + NO → S31a → IM31a + NO₂ are 9.50 kcal/mol and 78.87 kcal/mol, respectively. This low barrier energy and high exothermic energy in this process mean that the O atom abstraction by NO can occur easily. So this process is both thermodynamically and kinetically favorable. IM31a is a

kind of intermediates which contains group “ $\text{—}\overset{\text{O}}{\parallel}\text{C—O—}$ ” and is easy to hydrolyze.

Hasson et al. (2003) has studied the role of the water vapor in the alkene ozonolysis. It is pointed out that water vapor is an additional source of OH radicals in the reaction with criegee intermediates. The mechanism is proposed (**Fig. 5**) and the route R(1) is the most probable reaction channel.

IMa2 can react with H₂O to form a van der Waals complex IM3a, and then it will generate IM4a-OH via TS3a. In TS3a, the H atom of H₂O is transferred to the O atom of “C=O-O” and the OH group of H₂O approaches the C atom. The IM4a-OH will be decomposed quickly because it is a complex with rich energy. Then the OH radical will play a very important role in dioxin degradation. The energy barrier and exothermic energy of this process are 11.75 kcal/mol and 29.41 kcal/mol, respectively.

Fig. 4 Profile of potential energy surface for the Ima2 react with NO and H₂O.

Fig. 5 Possible reactions of Criegee intermediates with H_2O (Hasson et al., 2003).

2.2.2 Reaction of IMb21 and IMb22

In the ozonolysis reaction channel B, the Criegee intermediates generated from the reactions are IMb21 and IMb22. IMb21 can react with H_2O which is the same as the reaction of IMa2 with H_2O . The profile of the potential surface is given as follows:

While IMb22 can be abstracted by NO, which is similar to the reaction of IMa2 with NO.

Here, the property of IM32b is similar to that of IM31a discussed previously. The other Criegee intermediates produced in the ozonolysis reaction can also react with NO and H_2O , similar to the reaction of IMa2, IMb21 and IMb22.

2.3 Rate constants and atmospheric lifetimes

So far, the whole degradation mechanism is discussed in detail. The rate constants for the reaction of PCDD/Fs

with O_3 have been studied by many groups. Kwok et al. (1995) has reported the rate constant for the gas-phase reaction of debenzo-p-dioxin with O_3 at $297 \pm 2 \text{ K}$ and atmospheric pressure of air using a relative rate method. The rate constant is $< 5 \times 10^{-20} \text{ cm}^3 \text{ (mole-sec)}$ which is consistent with expectations based on kinetic data for gas phase reactions of O_3 with other aromatic compounds.

In this study, the RRKM theory modified by Hou and Wang (2007) is used to calculate the rate constants. The generally accepted temperature ranges from -56 to 15°C in the troposphere. Flue gas temperatures of 240 – 260°C are generally needed for effective PCDD/Fs destruction in field tests. Then a wider range of 200 – 600 K is chosen to study the relationship between the temperature and rate constants.

There are no previous data for the reaction of 2,3,7,8-TCDD + $\text{O}_3 \rightarrow \text{TS} \rightarrow \text{IM}$. The rate constants of each channel are listed in **Table 1**. The rate constants at 298.15 K are taken as examples.

The total rate constant design formula of 2,3,7,8-TCDD with O_3 is $k_{\text{total}} = (k_1 + k_4) \times 2 + (k_2 + k_3) \times 4$, i.e., about $4.80 \times 10^{-20} \text{ cm}^3/(\text{mole-sec})$, which is close to the experiment value ($5 \times 10^{-20} \text{ cm}^3/(\text{mole-sec})$) of the reaction of PCDD/Fs with O_3 , and the difference between rate constants may be attributed to the number of Cl atoms. It seems that the RRKM rate constants are reasonable.

Apart from the height of potential barriers, the rate constants are influenced significantly by the change of

Table 1 Rate constants of the elementary reaction of 2,3,7,8-TCDD with O_3 (unit: $\text{cm}^3/(\text{mole-sec})$)

| $T \text{ (K)}$ | $\text{R} + \text{O}_3 \rightarrow \text{TSa1} \rightarrow \text{IMa1}^a$ | $\text{R} + \text{O}_3 \rightarrow \text{TSb1} \rightarrow \text{IMb1}^b$ | $\text{R} + \text{O}_3 \rightarrow \text{TScl} \rightarrow \text{IMcl}^c$ | $\text{R} + \text{O}_3 \rightarrow \text{TSd1} \rightarrow \text{IMd1}^d$ | 2,3,7,8-TCDD + $\text{O}_3 \rightarrow \text{TS} \rightarrow \text{IM}^e$ |

^a $k(T) = 2.49 \times 10^{-13} \exp(-5188.93/T)$; ^b $k(T) = 1.00 \times 10^{-13} \exp(-4803.81/T)$; ^c $k(T) = 6.62 \times 10^{-13} \exp(-6286.89/T)$; ^d $k(T) = 3.66 \times 10^{-13} \exp(-6425.55/T)$; ^e $k(T) = 2.41 \times 10^{-12} \exp(-5014.17/T)$.

temperature. Evidently, the rate constants of path A and path B are larger than those of path C and path D in low temperature range. While the rate constants of path C are larger than those of path A, path B and path D in high temperature range. The branching ratios of the four paths are drawn in **Fig. 6**. The branching ratio of path A increase gradually with the temperature rising. The proportion of path A varies from 17% to 29% in the range of 200–600 K. The branching ratio of path B decreases gradually as the temperature rises, which takes up the largest proportion (83%) in 200 K and the smallest proportion (41%) in 600 K. The branching ratios of path C and path D increase gradually with the temperature rising and that of path C takes the largest proportion (25%) at 600 K. It can be seen that the different paths play different roles at different temperatures, and the different paths will lead to a different degradation mechanisms.

In order to further consider the role of NO, H₂O and O₃ on the criegee intermediates, the rate constants of IMA2 with NO, H₂O and O₃ are calculated. The values are listed in the **Table 2**, which can provide a reference for experimental data. For the above dimolecular reaction, the reaction velocity (ν) is

$$\nu = k[\text{IMa2}][X] \quad X = \text{NO, H}_2\text{O or O}_3 \quad (9)$$

Since the concentration of X can be taken as a constant in the troposphere, the dimolecular reactions approximate the first order reactions. Then the roles of NO, H₂O or O₃ are changed vary with their concentrations in atmosphere.

The calculated rate constants for the reactions are expressed in the Arrhenius form of $k = A\exp(-E_a/RT)$ (in cm³/(mole·sec)). The formula is given in **Tables 1** and **2**.

According to the rate constants of elementary reaction, the atmospheric lifetime of the reactants can be calculated (Sun et al., 2011). The lifetimes of the 2,3,7,8-TCDD and IMA2 over the range of 200–600 K are listed in **Table 3**. The lifetimes of reactants are helpful in the risk assessment of hazardous materials.

The lifetime of 2,3,7,8-TCDD relative to O₃ is 11.50

Fig. 6 Branching ratio of four reaction pathway at 200–600 K.

^a O₃ average concentration is about 7×10^{11} mole/cm³; ^b water average concentration is about 5.375×10^{17} mole/cm³; ^c NO average concentration is about 2.6875×10^{10} mole/cm³.

months at 298.15 K. The lifetimes of IMA2 relative to O₃, H₂O and NO are 21.05 years, 0.53 seconds and 30.09 years, respectively. Obviously, the water in atmosphere may play an important role in the degradation of IMA2.

The dioxins, including 2,3,7,8-TCDD, are distributed all over the atmosphere, such as gas phase, liquid phase, and the surface of gas-solid phase. The degradation mechanism in different phases should be further studied.

3 Conclusions

The ozonolysis mechanism of 2,3,7,8-TCDD is studied using the method of quantum chemistry calculation. The role of abundant precursors such as NO and H₂O in the atmosphere was also discussed. The rate constants were calculated using the RRKM theory at 200–600 K and the atmospheric lifetimes are estimated. The present study leads us to draw the following conclusions: (1) There are

existences of four reaction channels, any of which can take place. The potential barriers of four intramolecular reaction sites in 2,3,7,8-TCDD with the O₃ show that path A and path B are lower than those of path C and path D. (2) In the ozonolysis mechanism, the water is the source of the OH radical, which can initiate the subsequent degradation. (3) The total rate constant of 2,3,7,8-TCDD with O₃ is $4.80 \times 10^{-20} \text{ cm}^3/(\text{mole}\cdot\text{sec})$ and the lifetime is 11.50 months.

JOURNAL OF ENVIRONMENTAL SCIENCES

环境科学学报(英文版)
(<http://www.jesc.ac.cn>)

Aims and scope

Journal of Environmental Sciences is an international academic journal supervised by Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences. The journal publishes original, peer-reviewed innovative research and valuable findings in environmental sciences. The types of articles published are research article, critical review, rapid communications, and special issues.

The scope of the journal embraces the treatment processes for natural groundwater, municipal, agricultural and industrial water and wastewaters; physical and chemical methods for limitation of pollutants emission into the atmospheric environment; chemical and biological and phytoremediation of contaminated soil; fate and transport of pollutants in environments; toxicological effects of terrorist chemical release on the natural environment and human health; development of environmental catalysts and materials.

China: Please contact the customer service, Science Press, 16 Donghuangchenggen North Street, Beijing 100717, China. Tel: +86-10-64017032; E-mail: journal@mail.sciencep.com, or the local post office throughout China (domestic postcode: 2-580).

Outside China: Please order the journal from the Elsevier Customer Service Department at the Regional Sales Office nearest you.

Submission declaration

Submission of an article implies that the work described has not been published previously (except in the form of an abstract or as part of a published lecture or academic thesis), that it is not under consideration for publication elsewhere. The submission should be approved by all authors and tacitly or explicitly by the responsible authorities where the work was carried out. If the manuscript accepted, it will not be published elsewhere in the same form, in English or in any other language, including electronically without the written consent of the copyright-holder.
